Abstract

Tree-level accidental symmetries are known to play a fundamental role in the phenomenology of the Standard Model (SM) for electroweak interactions. So far, no significant deviations from the theory have been observed in precision, flavour and collider physics. Consequently, these global symmetries are expected to remain quite efficient in any attempt beyond the SM. Yet, they do not forbid rather unorthodox phenomena within the reach of current LHC experiments. This is illustrated with a vectophobic Two-Higgs-Doublet-Model (2HDM) where effects of a light, flavour-violating and custodian (pseudo)scalar might be observed in the $B_s \rightarrow \mu^+ \mu^-$ decay rate and in the diphoton invariant mass spectrum at around 125 GeV.

1 Introduction

Baryon number conservation, invoked [1] to explain the striking stability of the proton against $p \rightarrow e^+ \gamma$, played a crucial role in the building of the quark model and turned out to be a tree-level accidental symmetry of the SM. Indeed, its associated $U(1)_B$ group is only broken by very tiny quantum effects linked to the gauge coupling of $SU(2)_L$. Remarkably, once splitted into distinct sectors, the $SU(2)_L \times U(1)_Y$ gauge-invariant SM Lagrangian has progressively revealed other accidental global symmetries that are now quite useful for our understanding of electroweak processes among the three up and down quarks.

On the one hand, the so-called custodial symmetry is an accidental one arising from the Higgs potential of the SM. It has been identified [2] as the responsible for the amazing

*elvira.cervero@uclouvain.be

†jean-marc.gerard@uclouvain.be

success of the tree-level mass relation

$$\rho \equiv \frac{M_W^2}{M_Z^2 \cos^2 \theta_W} = 1 \quad (1)$$

with respect to the electroweak precision data. Indeed, its associated $SU(2)_{L+R}$ group is only explicitly broken by the up-down quark mass splittings, in the limit where the gauge coupling of $U(1)_Y$ can be neglected (or equivalently if $\theta_W \rightarrow 0$).

On the other hand, the large flavour symmetry [3] with unitary transformations acting respectively on the left-handed quark doublets, the right-handed charge $\frac{2}{3}$ quarks and the right-handed charge $-\frac{1}{3}$ quarks is an accidental symmetry in the Yang-Mills sector of the SM. It is used to classify all Flavour Changing Neutral Currents (FCNC) beyond tree-level in terms of the Cabibbo-Kobayashi-Maskawa (CKM) mixing matrix

$$V_{CKM} = U_L^u U_L^{d\dagger} \quad (2)$$

where the $U_L^{u,d}$ are misaligned unitary matrices relating the u_L and d_L weak eigenstates to their mass eigenstates. In other words, the CKM matrix is obviously invariant under the associated $U(3)_{Q_L} \times U(3)_{U_R} \times U(3)_{D_L}$ but these flavour groups are explicitly broken by the up-up (down-down) quark mass splittings.

In the SM, both the accidental (bosonic) custodial and (fermionic) flavour symmetries are violated by the Yukawa couplings of the single Higgs field to the quark ones, in a way consistent with all the available data. Naively, the safest way to go beyond the SM is to ensure a minimal violation of these global symmetries. Yet, this does not necessarily guarantee orthodoxy. Indeed, such an extension of the SM through the introduction of a second vectophobic Higgs doublet might already lead to non-standard $B_s \rightarrow \mu^+ \mu^-$ decay rate and two-photon invariant mass spectrum at running LHC experiments.

2 Custodial symmetry

If we impose a custodial symmetry on the 2HDM potential, the physical states can be classified in triplet and singlet irreducible representations of the unbroken $SU(2)_{L+R}$, namely

$$\Phi_1 \ni \left\{ \begin{array}{c} G^+ \\ G^0 \\ G^- \end{array} \right\} \oplus \{h^0 + \frac{v}{\sqrt{2}}\}; \quad v = (\sqrt{2}G_F)^{-\frac{1}{2}} \approx 246 \text{ GeV} \quad (3)$$

and

$$\Phi_2 \ni \left\{ \begin{array}{c} H^+ \\ A^0 \\ H^- \end{array} \right\} \oplus \{H^0\} \text{ or } \left\{ \begin{array}{c} H^+ \\ H^0 \\ H^- \end{array} \right\} \oplus \{A^0\}. \quad (4)$$

Retaining CP violation as part of flavour violation, we assume the spin-0 sector to be CP invariant with H^0 and A^0 the new scalar and pseudoscalar, respectively. These assignments with h^0 behaving as the SM scalar and all the new physical states beyond the SM being in

Φ_2 would correspond to a particular case of the so-called Higgs basis (defined by the angle β for the G^\pm - H^\pm and G^0 - A^0 mixings) with a further assumption on the H^0 - h^0 mixing angle, namely $\alpha = \beta - \frac{\pi}{2}$. The triplet in eq. (3) corresponds to the massless Nambu-Goldstone bosons. In the limit where the scalar triplet in eq. (4) is also degenerate in mass, the custodial $SU(2)_{L+R}$ symmetry is minimally broken like in the SM (i.e., by $m_b \ll m_t$ and $\theta_W \neq 0$) since Φ_2 is vectophobic and its quantum corrections to the ρ parameter cancel. In the following, we will assume that the singlet component of Φ_2 is light compared to its triplet partners, i.e.

$$m_{H^0} < m_{A^0} \approx m_{H^\pm} \quad \text{or} \quad m_{A^0} < m_{H^0} \approx m_{H^\pm}. \quad (5)$$

The SM-like h^0 mass remains a free parameter depending, in principle, on the (quasi) degeneracy of A^0 (H^0) and H^\pm through the ρ parameter. Note that the second, CP-twisted, case with a light pseudoscalar A^0 may also naturally arise either from a spontaneous symmetry breaking [4, 5] or from a dynamical [6] one. Yet, the option of a fundamental or effective Higgs potential is left open hereafter.

3 Flavour symmetries

In the custodial 2HDM characterized by eqs. (3) and (4), the Yukawa couplings are given by

$$\mathcal{L}_Y = -\bar{Q}'_L (Y'_d \Phi_1 + Z'_d \Phi_2) d'_R - \bar{Q}'_L (Y'_u \tilde{\Phi}_1 + Z'_u \tilde{\Phi}_2) u'_R + h.c. \quad (6)$$

Consequently, all the fermions acquire a mass through their coupling Y' to Φ_1 while tree-level FCNC are induced by their coupling Z' to the new spin-0 fields in Φ_2 . As these FCNC are very much constrained by experimental data, some mechanism must be found in order to suppress them. A popular way to forbid any FCNC at tree-level is the so-called Natural Flavour Conservation (NFC) hypothesis [7] based on a flavour blind symmetry. However, here, if the Higgs doublets have a different parity under the discrete group \mathbb{Z}_2 ($\Phi_1 \rightarrow \Phi_1$ and $\Phi_2 \rightarrow -\Phi_2$) the Z' couplings are not allowed, the vectophobic Φ_2 becomes also fermiophobic and we simply recover the flavour physics of the SM.

So, let us consider another way to tame but not eliminate FCNC at tree-level beyond the SM, namely the Minimal Flavour Violation (MFV) hypothesis [3, 8, 9, 10, 11]. To formulate the MFV hypothesis, one first considers the full flavour symmetry of the gauge sector. Although the Yukawa couplings explicitly break $G_f = SU(3)_{Q_L} \times SU(3)_{U_R} \times SU(3)_{D_R}$, this symmetry can be restored by imposing suitable transformation laws under G_f to them. By doing so, the Yukawa couplings are promoted into auxiliary fields or spurions

$$Y'_u \sim (3, \bar{3}, 1) \quad (7)$$

$$Y'_d \sim (3, 1, \bar{3}). \quad (8)$$

The three forsaken $U(1)$ symmetries can be rearranged to correspond respectively to the vectorial baryon number, the chiral hypercharge and the axial Peccei-Quinn charge,

$$U(1)^3 = U(1)_B \times U(1)_Y \times U(1)_{PQ}. \quad (9)$$

The MFV hypothesis as formulated in [12] and implemented here is based on two conditions:

- The new flavour structures beyond the SM must be invariant under the G_f group. To implement this first condition, the new flavour structures are written as a series in terms of the spurions. The minimality of the hypothesis is guaranteed by imposing that only the spurions needed to account for the fermion masses and mixings are allowed.
- The coefficients of the MFV expansion in terms of the spurions must be natural, i.e. $\mathcal{O}(1)$. This second condition is imposed to let the spurions be the only structures responsible for the masses and mixing hierarchies and to avoid any further fine-tuning.

In the SM, the $U(1)_Y$ is spontaneously broken since the Higgs doublet carries a non-zero hypercharge. In a general 2HDM, it is also possible to separate the breaking of the $U(1)_{PQ}$ by shifting the PQ charge of the spurions to the Higgs doublets. However, in eq. (6) only Φ_1 generates the quark masses and mixings such that the minimality requirement would then imply massless up or down quarks.

In the past, spurions were introduced for a straightforward isospin decomposition of the weak $K \rightarrow \pi\pi$ decay amplitudes or to provide Goldstone bosons with a small mass in a chiral invariant effective theory for strong interactions. In the first case, these spurions are just auxiliary fields with no physical meaning while in the second one, the light quark mass matrix promoted to a field is eventually related to the Higgs one. Here, MFV gives rise to an effective low-energy theory which does not make any assumption about the possible underlying high-energy dynamics of the spurions. They could well be the background values of new heavy scalar fields called flavons [13].

To apply the specific formulation of MFV given above to eq. (6), we simply have to express the new flavour structures Z'_i as series of the Y'_i couplings in a G_f invariant way. If we neglect down quark masses with respect to the top one, the Y'_d coupling can be set to zero inside the series. Using the Cayley-Hamilton relation for a 3×3 Hermitian matrix, we then obtain the following Yukawa couplings to Φ_2

$$Z'_d = \{\delta_0 + \delta_1 Y'_u Y'^{\dagger}_u + \delta_2 (Y'_u Y'^{\dagger}_u)^2\} Y'_d, \quad (10)$$

$$Z'_u = \{\nu_0 + \nu_1 Y'_u Y'^{\dagger}_u + \nu_2 (Y'_u Y'^{\dagger}_u)^2\} Y'_u. \quad (11)$$

In the aligned 2HDM [14, 15], the relations among the Yukawa couplings are equivalent to eqs. (10) and (11) when considering only δ_0 and ν_0 and allowing them to be complex. The other terms are all induced through quantum loop effects. In this limit, NFC is recovered and relations to the $\tan \beta$ ($\cot \beta$) coefficients for the various \mathbb{Z}_2 invariant Type-I and Type-II models can easily be established. We refer to [15] for these relations as well as for the limit imposed on the charged Higgs mass by the $\bar{B} \rightarrow X_s \gamma$ rare decay, namely

$$m_{H^\pm} \gtrsim 400 \text{ GeV} \quad (12)$$

for values of the MFV coefficients δ_i and ν_i close to one. Hereafter, we will saturate this bound by taking the mass of H^\pm and its custodial neutral partner (see eq. (5)) at 400 GeV.

Note that the new LHC bounds do not apply to the heavy $H^0(A^0)$ since it may decay in a non-standard way via $H^0(A^0) \rightarrow A^0(H^0)Z^0$.

In [8, 10], the $SU(2)_L \times U(1)_Y$ gauge-invariant operators are classified for a 2HDM with MFV. These dimension-six operators are Λ^{-2} suppressed only if the scale hierarchy $M_W \ll m_{H^0, A^0} \ll \Lambda$ is assumed. This effective approach differs from ours since we consider MFV with H^0 or A^0 lighter than the top quark and rather close to the W-mass scale. MFV has also been applied to 2HDM in [9]. However, there, the MFV hypothesis was formulated in the generic basis with CP violation in a Type-II model for large $\tan \beta$. Here, by formulating MFV directly in a CP-invariant and vectophobic basis, we have simply rotated away any $\tan \beta$ dependence.

In our vectophobic 2HDM, the down tree-level FCNC are induced by the following Yukawa interactions expressed in terms of the quark mass eigenstates

$$\mathcal{L}_Y^{FCNC} = -\bar{d}_L^i (Z_d)_{ij} d_R^j \left(\frac{H^0 + iA^0}{\sqrt{2}} \right) + h.c. \quad (13)$$

with

$$Z_d = 4G_F \delta_1 V_{CKM}^\dagger M_u^2 V_{CKM} \frac{M_d}{v}, \quad (14)$$

and $M_{u(d)}$, the diagonal up (down) quark mass matrix. Note that we have only taken into account the first non diagonal term in eq. (10). Indeed, the huge mass hierarchy in the up sector implies that $(Y_u^\dagger Y_u)^2$ is almost aligned to $Y_u^\dagger Y_u$ in the three dimensional flavour space and the naturalness principle imposes that the δ_i and the v_i are $\mathcal{O}(1)$. If we only consider the leading contribution from the top quark mass, the Z_d coupling can be expressed like

$$(Z_d)_{ij} = 4G_F \delta_1 (V_{ti}^* V_{tj}) m_t^2 \frac{m_{d_j}}{v}. \quad (15)$$

In eq. (11), the up tree-level FCNC are simply absent. This implies that we will not consider the D^0 meson mixing and decays which are anyway polluted by sizeable long-distance effects.

3.1 $\Delta F = 2$ mixings

In the following, we analyse the implications of our custodial 2HDM with MFV in a few $\Delta F = 2$ quantities. In particular, new contributions to the B_s meson mass difference as well as to the $|\epsilon_K|$ parameter that estimates the amount of CP violation in the neutral Kaon system will be studied. In the SM, these quantities are dominated by short distance (SD) transitions and mainly induced through virtual top quark box diagrams.

The $\Delta F = 2$ effective Hamiltonian associated to the Yukawa interactions given in eq. (13) reads

$$\mathcal{H}_{2HDM}^{\Delta F=2} = \left(-\frac{1}{m_{H^0}^2} \frac{[(Z_d)_{ij} - (Z_d^\dagger)_{ij}]^2}{2} + \frac{1}{m_{A^0}^2} \frac{[(Z_d)_{ij} + (Z_d^\dagger)_{ij}]^2}{2} \right) (\bar{d}_R^i d_L^j)(\bar{d}_R^i d_L^j). \quad (16)$$

Within the SM, the SD $\Delta F = 2$ transitions take place through the one-loop box diagrams and the corresponding effective Hamiltonian is proportional to the operator $\mathcal{O}_{SM} = (\bar{d}^i \gamma^\mu \gamma_L d^j)(\bar{d}^i \gamma_\mu \gamma_L d^j)$. At the hadronic level, using eq. (15) and with the help of the Dirac equation, one can thus express the matrix element for eq. (16) as follows

$$\langle \bar{M}^0 | \mathcal{H}_{2HDM}^{\Delta F=2} | M^0 \rangle \simeq \frac{8G_F^2 \delta_1^2 (V_{ti}^* V_{tj})^2 m_t^4 m_M^2}{v^2} \left[\frac{(m_{d_i} - m_{d_j})^2}{(m_{d_i} + m_{d_j})^2} \frac{1}{m_{H^0}^2} - \frac{1}{m_{A^0}^2} \right] \langle \bar{M}^0 | \mathcal{O}_{SM} | M^0 \rangle. \quad (17)$$

For K^0 ($\bar{s}u$) and B_q^0 ($\bar{b}q$) mesons, the down quark mass hierarchy ($m_d \ll m_s \ll m_b$) allows us to consider the limit $m_{d_j} \ll m_{d_i}$ and we get

$$\langle \bar{M}^0 | \mathcal{H}_{eff}^{\Delta F=2} | M^0 \rangle \simeq \langle \bar{M}^0 | \mathcal{H}_{eff}^{\Delta F=2} | M^0 \rangle^{SM} \left[1 + 16\pi^2 x \delta_1^2 m_M^2 \left(\frac{1}{m_{H^0}^2} - \frac{1}{m_{A^0}^2} \right) \right]. \quad (18)$$

In eq. (18), the factor $16\pi^2$ stems from the SM one-loop contribution while x encodes the full dependence on the top quark mass ($m_t(m_t) = 163.3$ GeV)

$$x = \frac{2m_t^4}{M_W^2 v^2 S_0(x_t)} \approx 1.61. \quad (19)$$

The sign of the CP-odd ($-$) A^0 and CP-even ($+$) H^0 exchange contributions in eq. (18) can easily be understood by comparing with the general expression for any long-distance (LD) contributions to a $\Delta F = 2$ transition [16]

$$\langle \bar{M}^0 | \mathcal{H}_{eff}^{\Delta F=2} | M^0 \rangle_{LD} = \sum_I \left(\frac{|\langle M(-) | \mathcal{H}^{\Delta F=1} | I(-) \rangle|^2}{m_M - E_{I(-)} + i\epsilon} - \frac{|\langle M(+) | \mathcal{H}^{\Delta F=1} | I(+) \rangle|^2}{m_M - E_{I(+)} + i\epsilon} \right), \quad (20)$$

in the limit of CP-invariance. For illustration, in the case of the K_L - K_S mass difference, the single pseudoscalar exchange LD contribution is positive for the pion (lighter than the kaon) but negative for the $\eta^{(\prime)}$ (heavier than the kaon) [17], leading to a rather strong cancellation in the chiral perturbation theory [18].

The measured $|\epsilon_K|$ parameter in the K^0 - \bar{K}^0 system would alone clearly welcome some enhancement, i.e. a rather light H^0 , to relax a potential tension within the SM [19, 20]. However, as displayed in figure 1, the \bar{B}_s - B_s system already excludes such a scenario. In fact, eq. (18) directly tells us what will be the effect of a light H^0 or A^0 on the various $\Delta F = 2$ systems. Indeed, the new term with respect to the SM contribution is proportional to the square of the meson mass m_M . Such a feature implies a bigger effect in the B-meson system case than in the Kaon one and almost no difference between the B_d and B_s systems. Contrariwise, in the decoupling limit with $m_{A^0} = m_{H^0} \approx \Lambda$, eq. (17) tells us that any correction with respect to the SM should scale as $\left(\frac{m_{d_j}}{m_{d_i}} \right) \left(\frac{m_M^2}{\Lambda^2} \right) \ll 1$.

Figure 1: $|\epsilon_K|$ and ΔM_{B_s} as a function of the H^0 and A^0 masses for a MFV coefficient $\delta_1 = 1$. The green lines indicate the experimental values, the orange areas indicate the 1σ SM prediction, the blue areas show the 1σ prediction for $m_{H^0} \ll m_{A^0} = 400$ GeV, while the grey areas correspond to the analogue prediction for $m_{A^0} \ll m_{H^0} = 400$ GeV. The theoretical values of the SM and the experimental ones are given in Tab.1.

3.2 The $B_s \rightarrow \mu^+ \mu^-$ decay

In the SM, the rare $B_s \rightarrow \mu^+ \mu^-$ decay takes place through box and penguin diagrams, leading to an effective Hamiltonian proportional to the single operator

$$Q_A = (\bar{b}_L \gamma^\mu s_L)(\bar{\mu}_L \gamma_\mu \mu_L). \quad (21)$$

However, when introducing new physics beyond the SM, contributions from other operators can be sizeable. In the specific 2HDM under scrutiny, tree-level flavour changing neutral Higgs exchanges induce the following new operators

$$Q_S = m_b(\bar{b}_R s_L)(\bar{\mu} \mu) \quad (22)$$

$$Q_P = m_b(\bar{b}_R s_L)(\bar{\mu} \gamma_5 \mu). \quad (23)$$

In order to compute the branching ratio associated to this decay, MFV needs to be introduced in the lepton sector as well. This can be done in analogy with the quark sector. Yet, the specific lepton mass spectrum allows us to truncate the MFV series for Z_ℓ at first order

$$Z_\ell = \lambda_0 Y_\ell. \quad (24)$$

In any model where the operators in eqs. (22) and (23) give non-negligible contributions, the branching ratio can be expressed as follows

$$\mathcal{B}(B_s \rightarrow \mu^+ \mu^-) = \mathcal{B}(B_s \rightarrow \mu^+ \mu^-)^{SM} \left[\left(1 - \frac{m_{B_s}^2 C_P}{2m_\mu C_A} \right)^2 - \left(1 - \frac{m_{B_s}^2}{4m_\mu^2} \right) m_{B_s}^2 \frac{C_S^2}{C_A^2} \right] \quad (25)$$

where $C_A = 4Y(x_t) \approx 4.01$ is the Wilson coefficient associated to the SM operator. In our 2HDM, the coefficients C_S and C_P are given by

$$C_S = \frac{\Delta}{m_{H^0}^2}; \quad C_P = \frac{\Delta}{m_{A^0}^2}; \quad \Delta = -\frac{4\sqrt{2}\pi\delta_1\lambda_0 m_\mu m_t^2 \sin^2 \theta_W}{G_f \alpha v^4}. \quad (26)$$

Figure 2: The $B_s \rightarrow \mu^+ \mu^-$ branching ratio as a function of the H^0 and A^0 masses for the MFV coefficients $\delta_1 = \lambda_0 = 1$. The green line indicates the experimental upper bound value, the orange area indicates the 1σ SM prediction, the blue area shows the 1σ prediction for $m_{H^0} \ll m_{A^0} = 400$ GeV, while the grey area corresponds to the analogue prediction for $m_{A^0} \ll m_{H^0} = 400$ GeV. The theoretical value of the SM and the experimental bound are given in Tab.1.

From eq. (25) we expect quite different behaviours depending on whether the lightest spin-0 particle is A^0 or H^0 . Indeed, the SM Q_A operator only interferes with the A^0 -induced Q_P . Consequently, the $B_s \rightarrow \mu^+ \mu^-$ branching ratio is linear in C_P but quadratic in C_S . That explains why, in figure 2, the contribution of a 2HDM with A^0 the lightest flavour-violating spin-0 particle is more important

To summarize this section on flavour physics, let us emphasize once more that within MFV, the expansion coefficients in eqs. (10) and (11) are $\mathcal{O}(1)$ to fulfill the naturalness condition. To display the possible effect of a custodial 2HDM on K and B physics, we have simply taken $\delta_1 = \lambda_0 = 1$ in Fig.1 and 2. With these values, the B_s mixing provides a lower bound around 150 GeV for the lightest H^0 or A^0 . However, given the theoretical uncertainties, if these coefficients are slightly smaller (say 1/2), flavour physics alone would still allow for m_{H^0, A^0} around 100 GeV. Yet, in this case the constraint from $B_s \rightarrow \mu^+ \mu^-$ becomes weaker than the one displayed in Fig.2 and demands a precision on the branching ratio that may be difficult to achieve within the LHC.

SM predictions	Measurements
$ \epsilon_K _{SM} = 1.82(29) \times 10^{-3}$	$ \epsilon_K _{exp} = 2.228(11) \times 10^{-3}$ [21]
$(\Delta M_s)_{SM} = 119.1(16.6) \times 10^{-13}$ GeV	$(\Delta M_s)_{exp} = 117.0(0.8) \times 10^{-13}$ GeV [21]
$\mathcal{B}(B_s \rightarrow \mu^+ \mu^-)_{SM} = (3.9 \pm 0.6) \times 10^{-9}$	$\mathcal{B}(B_s \rightarrow \mu^+ \mu^-)_{exp} < 1.08 \times 10^{-8}$ @ 95% CL [22]

4 Two-photon signal(s) at the LHC

Recently, the ATLAS [23] and CMS [24] LHC experiments at CERN have reported an excess of events in the two-photon invariant mass spectrum at around 125 GeV. The possibility that the A^0 or H^0 present in a 2HDM is responsible for such a signal has already been considered in [25] and [26], respectively. Let us briefly (re)consider these possibilities in the context of our custodial 2HDM characterized by eqs. (3) and (4).

In the SM, the Φ_1 doublet alone is responsible for the gauge boson and matter particle masses [27]. As a consequence, h^0 is both vecto and fermiophilic and the dominant contributions to the diphoton events are due to top and W loops. In the 2HDM advocated here, the H^0 and A^0 are vectophobic (i.e. $g_{HVV} = g_{AVV} = 0$ with $V = W^\pm, Z^0$) and only the top contributes.

The number of events in the diphoton invariant mass spectrum is proportional to the production cross-section times the decay branching ratio. Remarkably, the ratio normalized to the SM rate

$$R = \frac{\sigma \times \mathcal{B}(H^0, A^0 \rightarrow \gamma\gamma)}{\sigma \times \mathcal{B}(h^0 \rightarrow \gamma\gamma)^{SM}} \quad (27)$$

is rather sizeable and quite stable for spin-0 particles with a mass running from 0 to 125 GeV

$$R_{H^0/h^0}(m_{H^0} = 0 \rightarrow 125 \text{ GeV}) = (0.12 \rightarrow 0.08) \frac{(v_0 + v_1 y_t^2)^4}{(\delta_0 + \delta_1 y_t^2)^2} \quad (28)$$

$$R_{A^0/h^0}(m_{A^0} = 0 \rightarrow 125 \text{ GeV}) = (0.59 \rightarrow 0.44) \frac{(v_0 + v_1 y_t^2)^4}{(\delta_0 + \delta_1 y_t^2)^2}, \quad (29)$$

if the production is dominated by gluon-gluon fusion via a top quark loop and if the total decay widths are dominated by the $b\bar{b}$ final state. In eqs. (28) and (29), $y_t = \frac{\sqrt{2}}{v} m_t$ is the top Yukawa coupling. This striking feature is due to the fact that the two-gluon and the two-photon couplings of a light spin-0 particle are determined by the so-called axial and scale anomalies. The corresponding effective Lagrangians describing these anomalies for $m_{H^0, A^0} \ll 2M_W, 2m_t$ are [28]

$$\mathcal{L}_{(H^0, A^0)\gamma\gamma} = \frac{\alpha_{em}}{2\pi} \frac{1}{v} \{c_{\gamma\gamma}(+) H^0 F^{\mu\nu} F_{\mu\nu} + c_{\gamma\gamma}(-) A^0 F^{\mu\nu} \tilde{F}_{\mu\nu}\} \quad (30)$$

$$\mathcal{L}_{(H^0, A^0)gg} = \frac{\alpha_s}{12\pi} \frac{1}{v} \{c_{gg}(+) H^0 G^{a\mu\nu} G_{\mu\nu}^a + c_{gg}(-) A^0 G^{a\mu\nu} \tilde{G}_{\mu\nu}^a\} \quad (31)$$

with $\mathcal{O}(1)$ c -coefficients given by

$$c_{\gamma\gamma}(+) = \frac{N_c}{3} q_t^2 - \frac{7}{4} \quad ; \quad c_{\gamma\gamma}(-) = \frac{N_c}{4} q_t^2 \quad (32)$$

$$c_{gg}(+) = 1 \quad ; \quad c_{gg}(-) = \frac{3}{2}. \quad (33)$$

In eq. (32), $q_t = \frac{2}{3}$ is the electric charge of the top quark while the second term of $c_{\gamma\gamma}(+)$ comes from the W-loop which is absent in the case of a vectophobic scalar H^0 .

Figure 3: The ratio R defined in eq. (27) as a function of the H^0 and A^0 masses if the MFV coefficients are equal to one. The black curve corresponds to the case where A^0 is the lightest non-SM Higgs boson while the blue one corresponds to the case where H^0 is the lightest non-SM Higgs boson.

In figure 3, the analytical expressions (explicitly given in [25]) have been used to plot the ratio R as a function of the (pseudo)scalar mass. An interesting feature of our 2HDM is that the ratio R is of order one because of the naturalness principle of MFV ($\delta_i, v_i \approx 1$). In the scalar case (i.e. H^0 -dominated), the number of events is expected to be smaller than in the SM even for large values of the MFV coefficients. The pseudoscalar case (i.e. A^0 -dominated), on the contrary, is quite compatible with $R = 1$ at 125 GeV for natural values of the v_i and δ_i coefficients. It would also be able to account for a possible excess with respect to the SM expectation.

Two possible *custodial* scenarios with a light vectophobic $A^0(H^0)$ are thus within the reach of the present LHC data. The first one would correspond to the following mass hierarchy

$$m_{A^0(H^0)} < m_{H^0(A^0)} \approx m_{H^\pm} < m_{h^0} \quad (34)$$

with the h^0 mass in any case above the $A^0 A^0(H^0 H^0)$ threshold to avoid the LHC bounds on a heavy SM-like Higgs boson, and with a small mass-splitting between the custodian $A^0(H^0)$ and H^\pm to satisfy the bounds from electroweak precision data. The second one would correspond to

$$m_{h^0}, m_{A^0(H^0)} < m_{H^0(A^0)} = m_{H^\pm} \quad (35)$$

with now two light resonances to be seen in the diphoton invariant mass spectrum. Needless to say that the forthcoming LHC results on Vector-boson fusion at the production level and on Vector-Vector final states at the decay level will be critical for these vectophobic scenarios. In particular, any excess from VV production or decay at around 125 GeV would rule out the scenario in eq. (34) but not the one in eq. (35) if the custodian $A^0(H^0)$ and H^\pm are now sufficiently degenerated in mass to allow a light SM-like h^0 compatible with the ρ parameter.

5 Conclusion

In this paper, we have considered a vectophobic 2HDM with a minimal violation of the flavour and custodial symmetries accidentally present in the SM.

On the one hand, the B_s mass difference provides us with the strongest indirect constraint on a light flavour-violating (pseudo)scalar. However, given the present theoretical uncertainties on the $\Delta F = 2$ weak processes, $B_s \rightarrow \mu^+ \mu^-$ might be the most appropriate decay to disentangle a A^0 -induced tree-level FCNC from a H^0 one in this model. On the other hand, a direct way to test the model proposed in this work is the diphoton invariant mass spectrum at the LHC. In particular, the light custodian pseudoscalar A^0 could even allow for a two-photon excess with respect to the SM expectation. However, the A^0 and H^0 particles being vectophobic, any evidence of W^+W^- or Z^0Z^0 gauge boson contributions at the production or decay level would also require a light SM-like scalar, namely a second diphoton signal. Finally, let us underline that other channels could provide interesting signatures at the LHC. In particular, the allowed H^0 - A^0 - Z^0 coupling might induce a sizable contribution to the $Z(\ell\bar{\ell})b\bar{b}$ cross-section as already emphasized in [5].

Acknowledgments

We would like to thank Fabio Maltoni and Christopher Smith for very useful discussions. The work of EC is supported by the F.R.I.A.
